# Outline

**UNESE Phase 2: The goal of this experiment was to learn about radioactive gas transport around a historic, horizontally emplaced, underground nuclear explosion.**

- History: UNESE Phase 1
- UNESE Phase 2 Injection
- Sampling
  - P-tunnel
  - Aqueduct Mesa
- Measurements results
  - P-tunnel
  - Aqueduct Mesa
- Future Work

## Large Volume Gas Samples Exiting P-Tunnel Portal

# History: UNESE Phase 1

## Noble Gas Migration Experiments 1 & 2

### Emplacement:

- A vertically emplaced test
- Gaseous tracers placed within partially collapsed cavity

### Experiment campaigns:

- 2012: Only surface sampling
- 2016: No cavity pressurization

### Samples collected for 13 months after injection

- Large volume (2m<sup>3</sup>) samples for radiotracers
- Small volume (~1L) samples for stable tracers

## Experiment Results

In 2012 experiment, Xe and Ar were observed to behave similarly- both depleted with respect to SF<sub>6</sub>

In 2016 experiment later samples were not depleted in Ar

Combination of factors needed to account for differences in observed gas arrivals.

## Conclusions

1. 2012 results more representative of *bulk advective transport* from pressurization of remaining chimney gas
2. 2016 results more representative of gas transported by *seepage flow*

# UNESE Phase 2

## P-tunnel tracer experiments

### Emplacement:

- A horizontally emplaced test
- Gaseous tracers placed within partially collapsed chimney

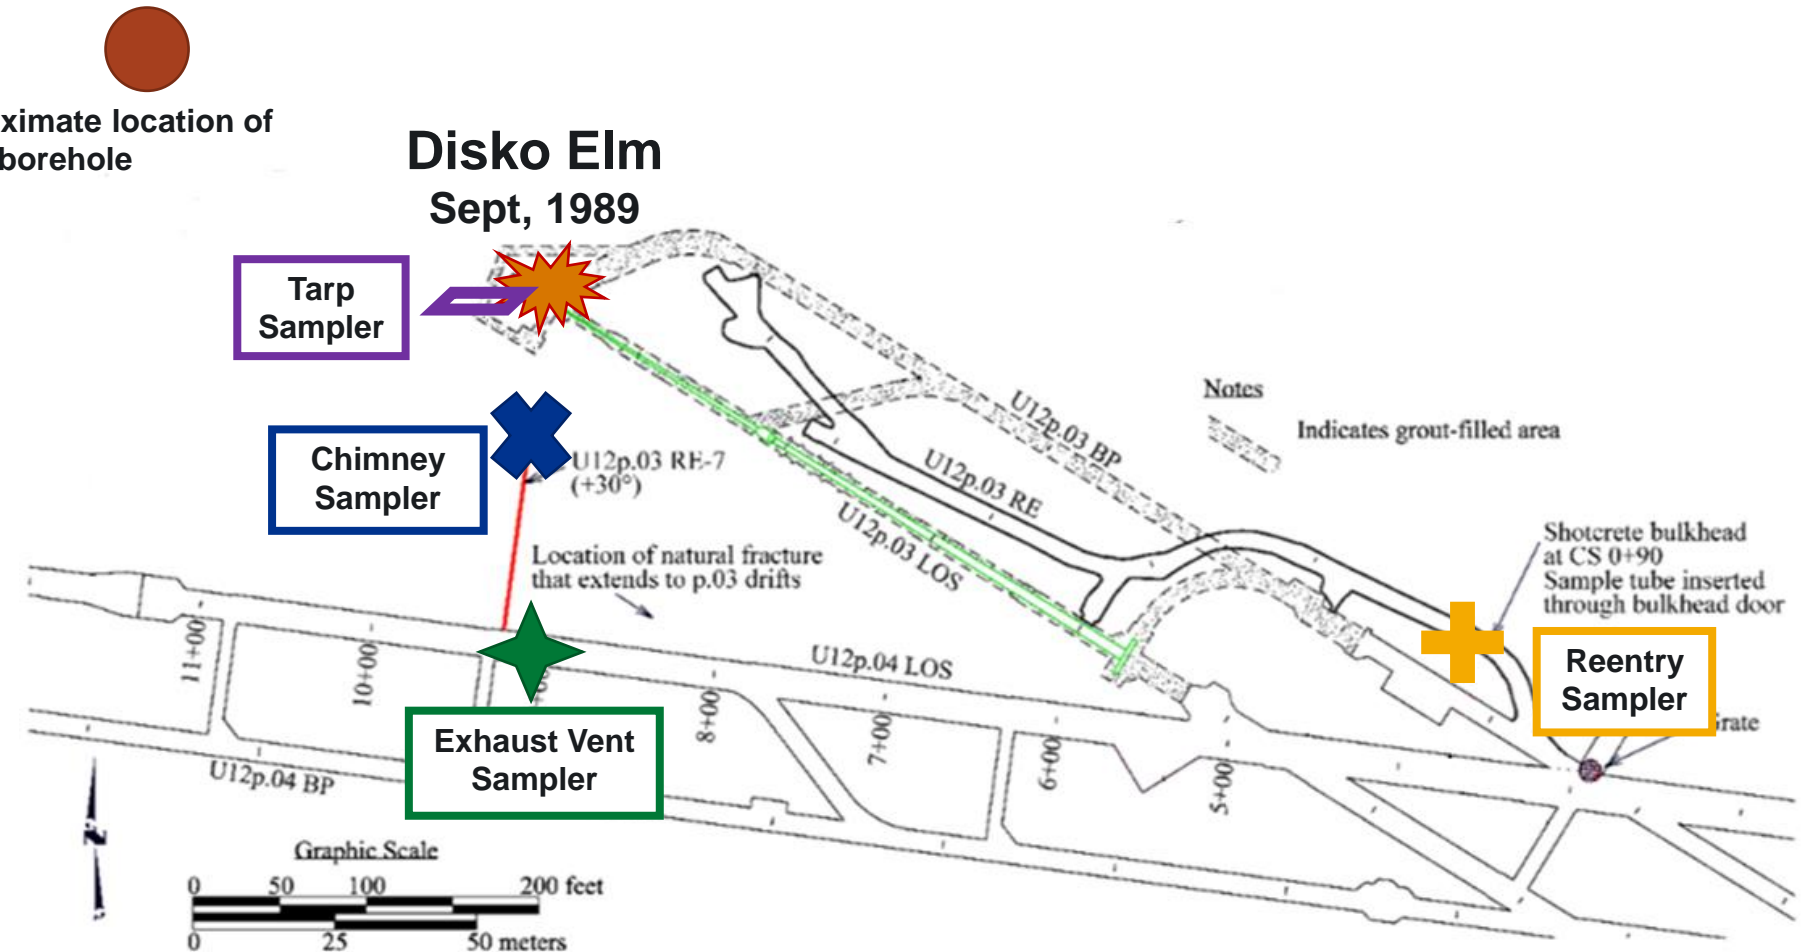

### Injection

- Two tracer injections
- Stable tracers
- Radioactive tracers injected with constant activity/time

### Sampling

- Three sampling locations in tunnel
- Four sampling location zones in borehole from surface
- Surface sampling outside tunnel portal and on mesa top

Approximate location of mesa borehole

## P-tunnel sampling locations

# Radionuclide and stable gas injection

Chimney injection (location ) lasted 4.5 hours on the morning of June 20, 2018.  
3 tracers injected

Mixed  $^{127}\text{Xe}$  and  $^{37}\text{Ar}$  (shown below in shielded canisters) injected with air.

- Approximately 20 GBq of each isotope
- Constant activity injection

Stable  $\text{SF}_6$  (~50 kg) injected with the mixed radiotracers.

Cylinder containing  $\text{SF}_6$  connected to the injection borehole shown below.

# P-tunnel sampling locations

Approximate location of mesa borehole ●

## Chimney Sampler: ✖

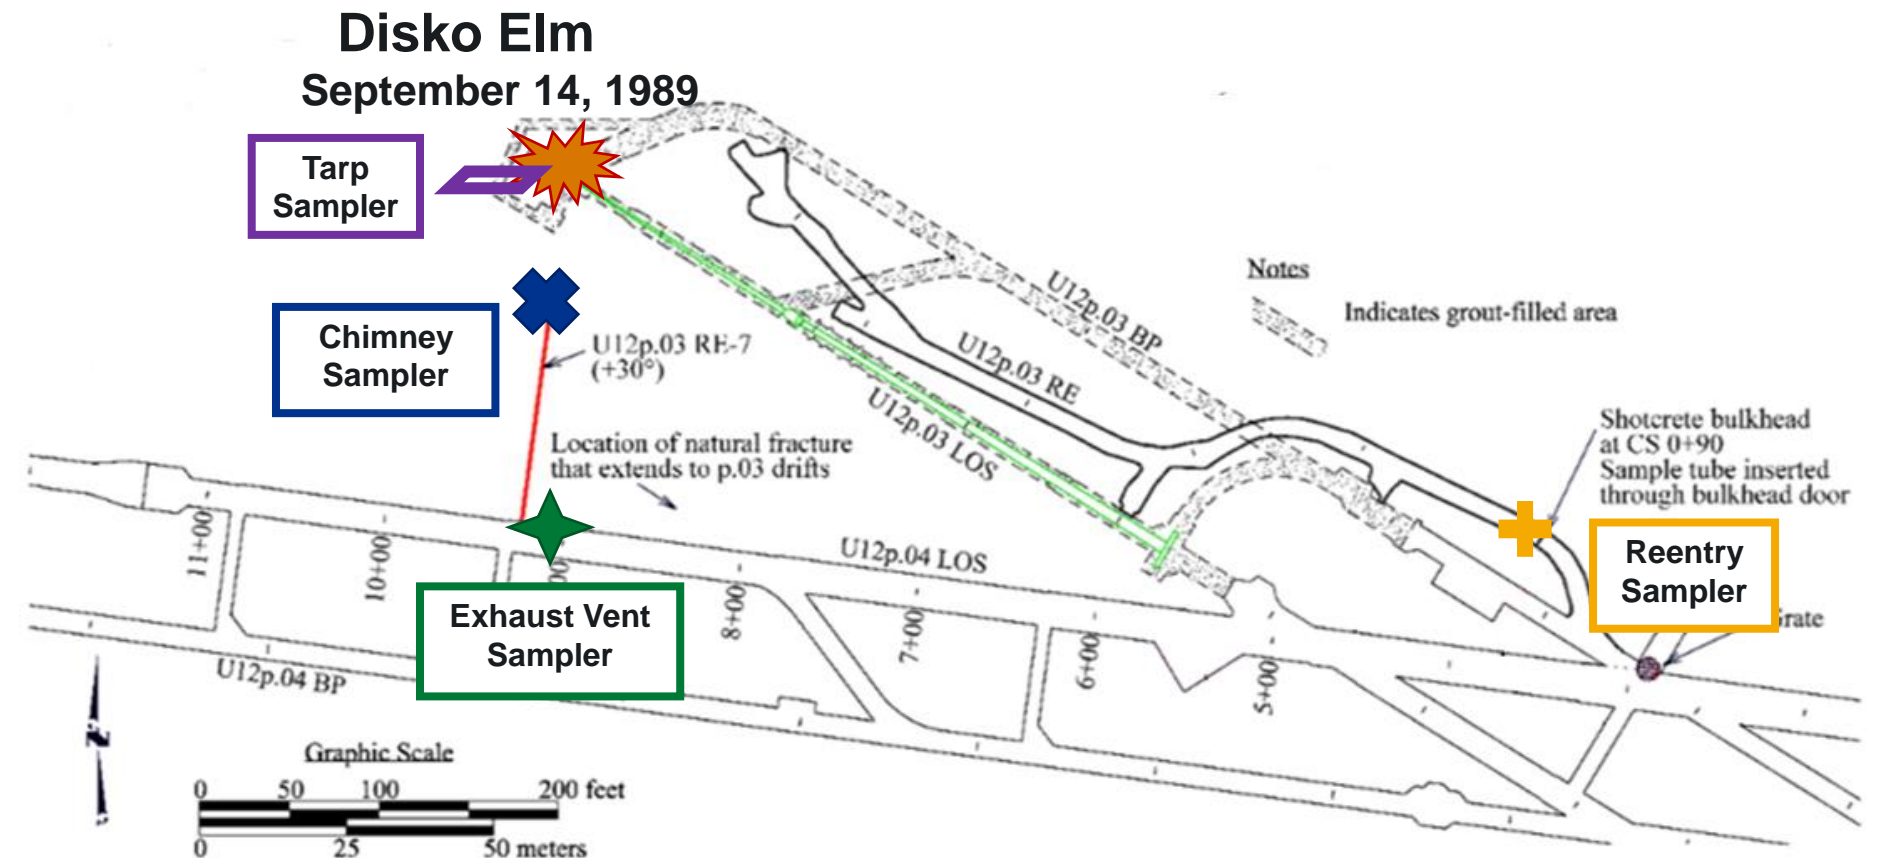

- Recirculating gas sampler
- Near-continuous  $^{127}\text{Xe}$  detection with NaI detector surrounded by gas volume
- Small samples collected from recirculation line

## Exhaust Vent Sampler: ✦

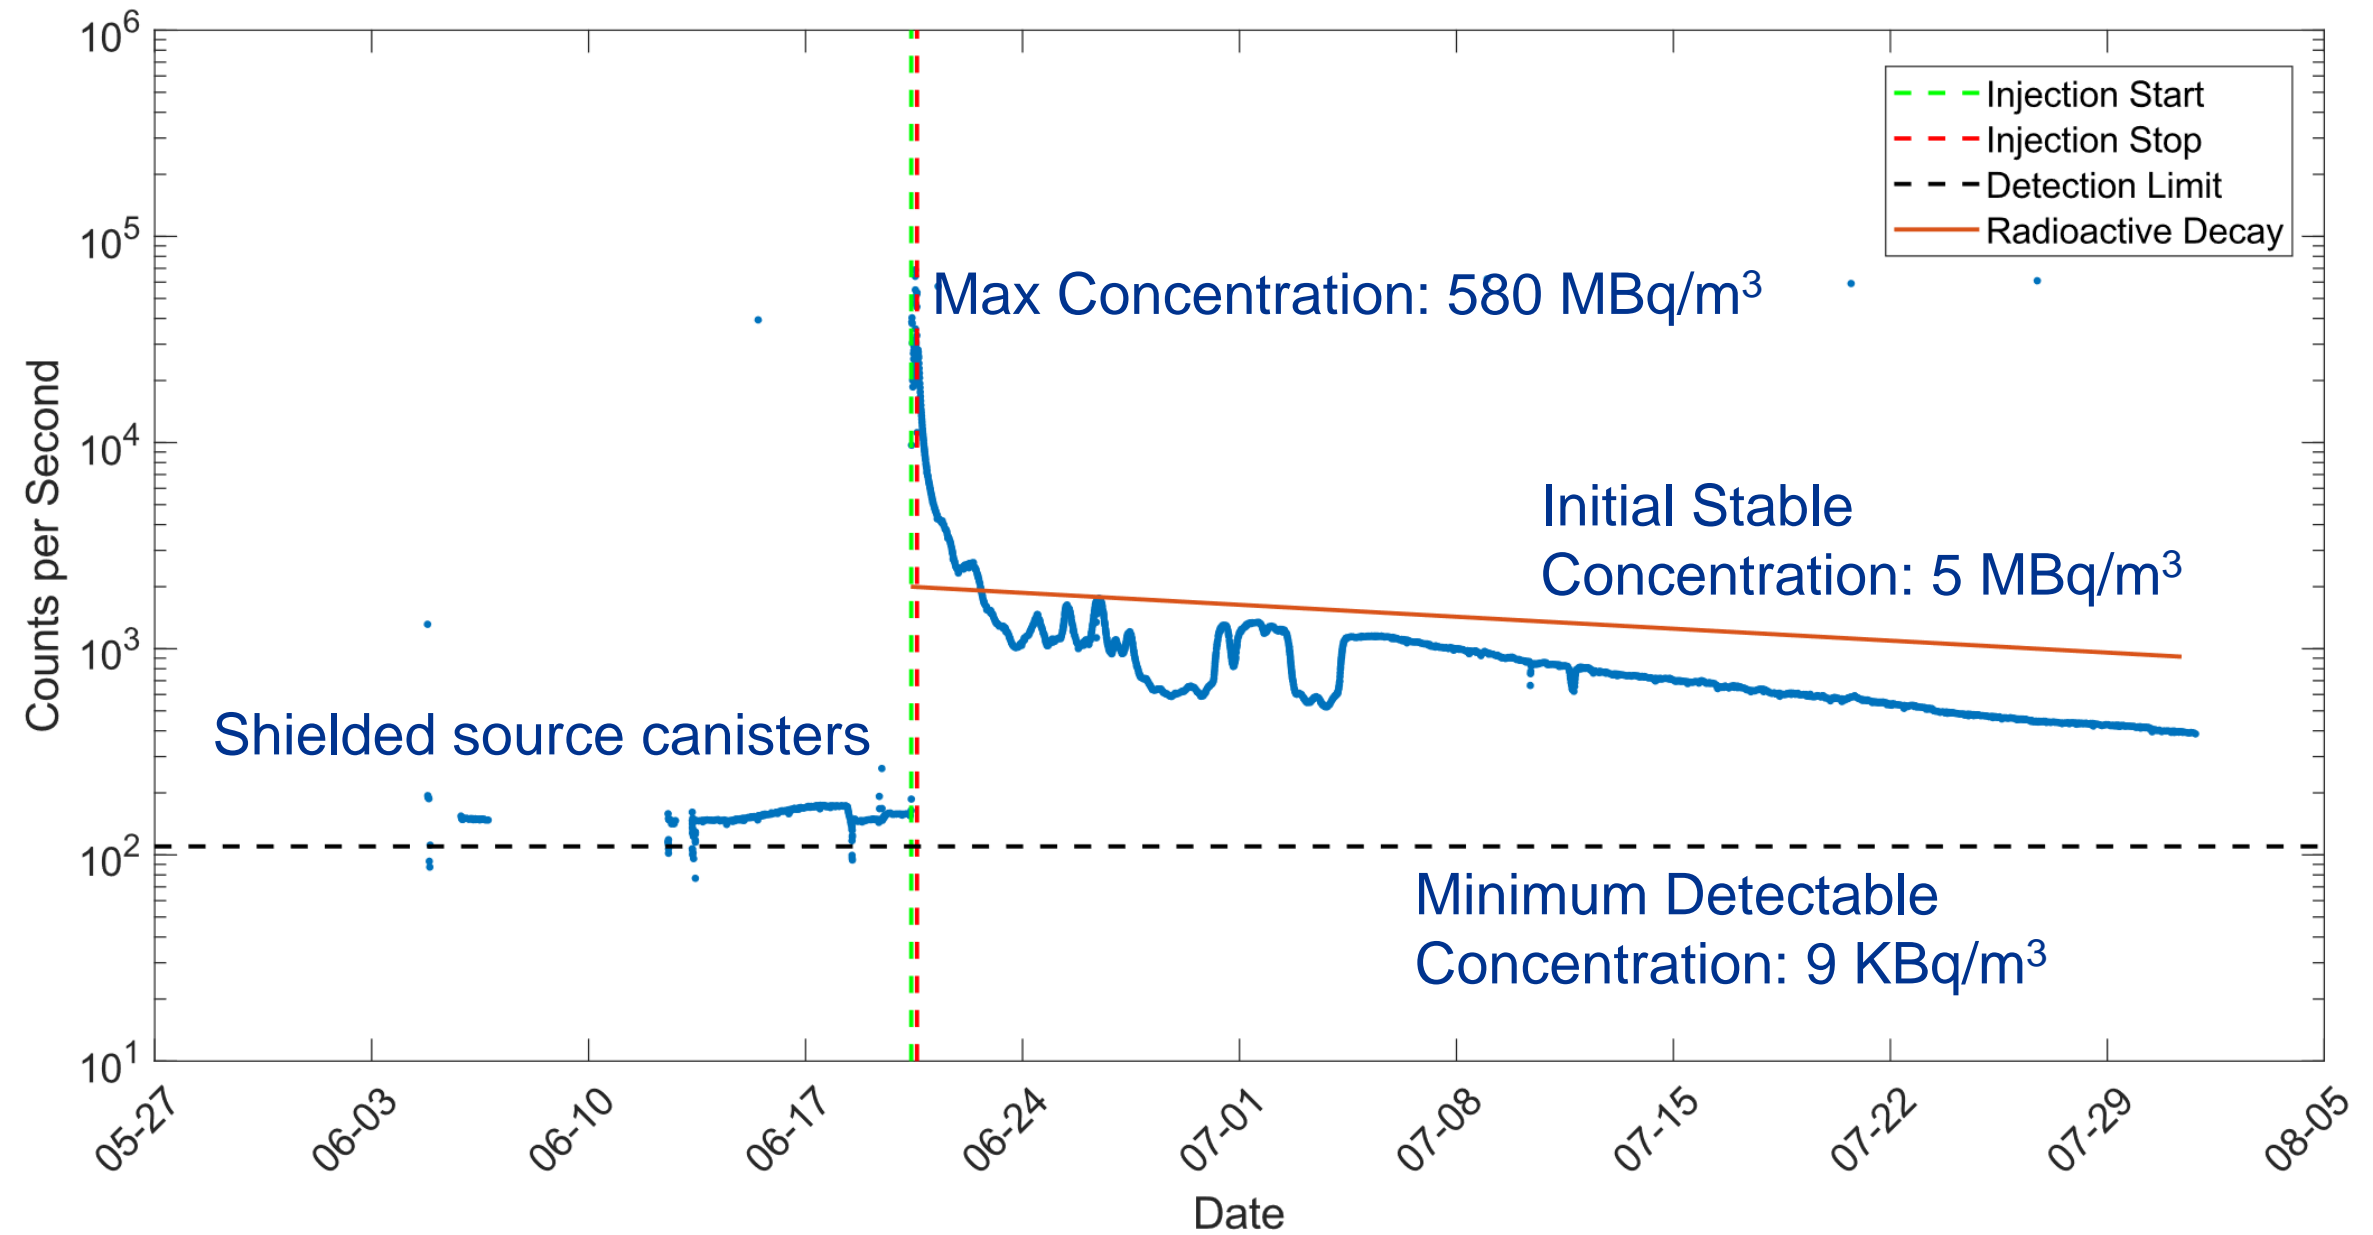

- Small samples collected from exhaust intake

## Reentry Sampler: +

- Recirculating gas sampler
- Near-continuous  $^{127}\text{Xe}$  detection with CsI detector surrounded by gas volume
- Small samples from parallel sampling line

# $^{127}\text{Xe}$ within the chimney ✖ (About 30m from WP)

# Measurements of $^{37}\text{Ar}$ in P-tunnel

Initial measurements of  $^{37}\text{Ar}$  made rapidly on-site with a field deployable  $^{37}\text{Ar}$  detector system

- All P-tunnel samples collected after injection had a volume of 1 L
- Injected  $^{37}\text{Ar}$  was detected in P-tunnel  $\star$  ventilation
  - possibly leakage from the injection borehole
- No  $^{37}\text{Ar}$  was detected in re-entry drift  $\oplus$

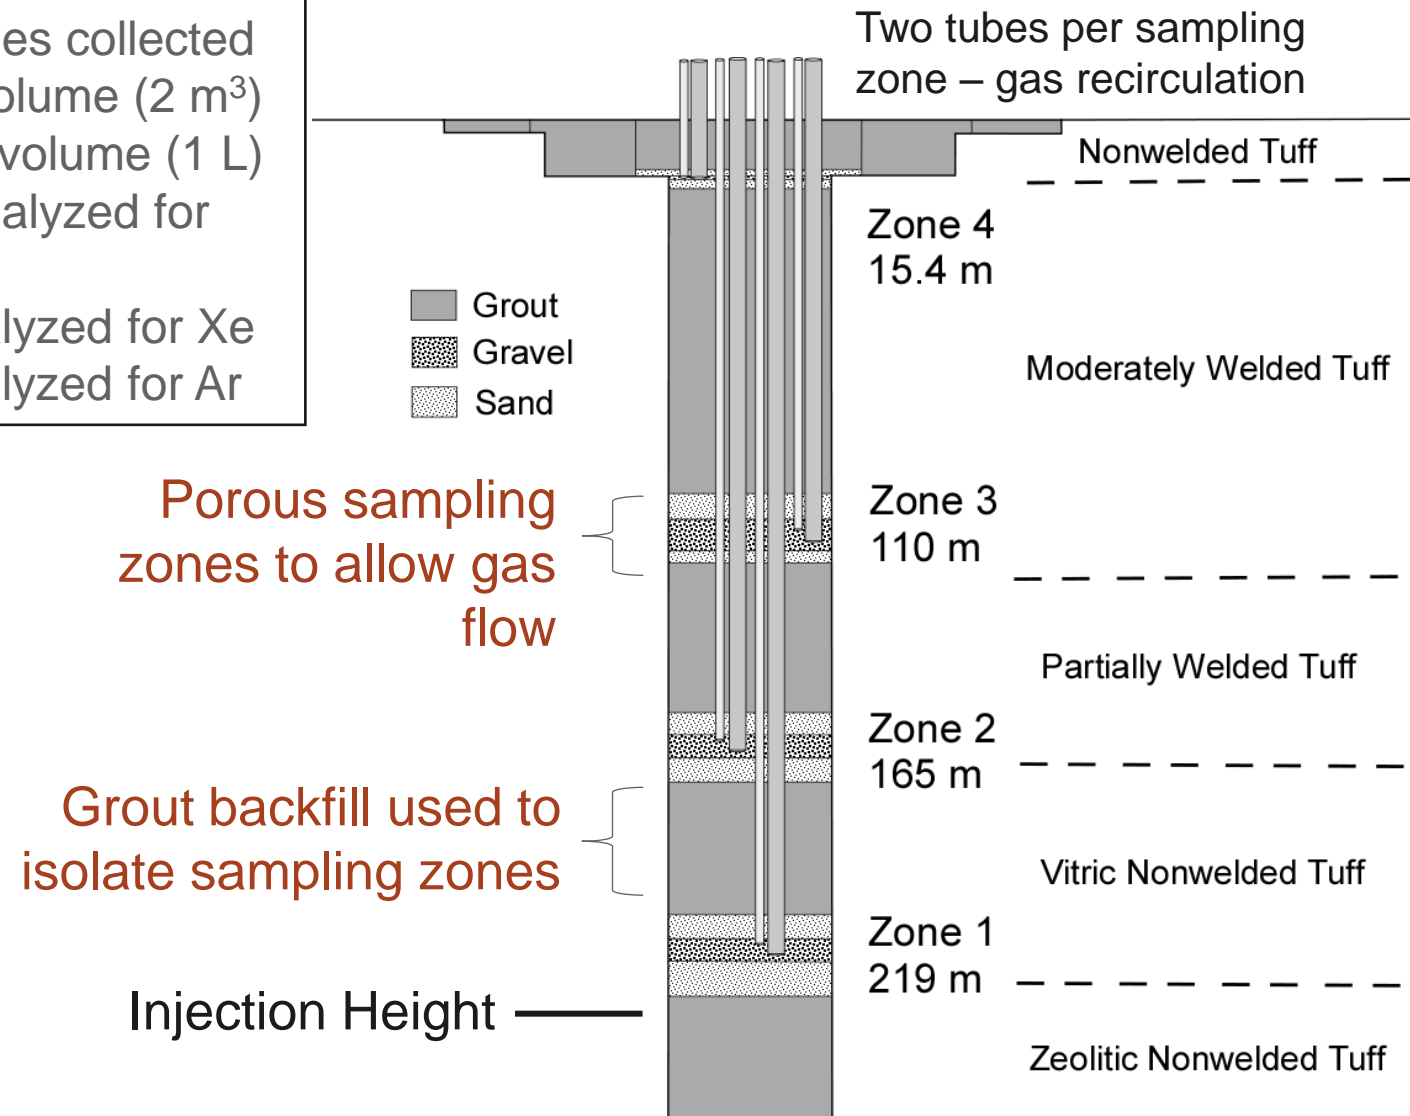

## $^{37}\text{Ar}$ in Ventilation Exhaust $\star$

# Aqueduct Mesa Sampling

- Over 200 samples collected
  - 50 large volume (2 m<sup>3</sup>)
  - 165 small volume (1 L)
- 100 samples analyzed for stable tracers
- 20 samples analyzed for Xe
- 30 samples analyzed for Ar

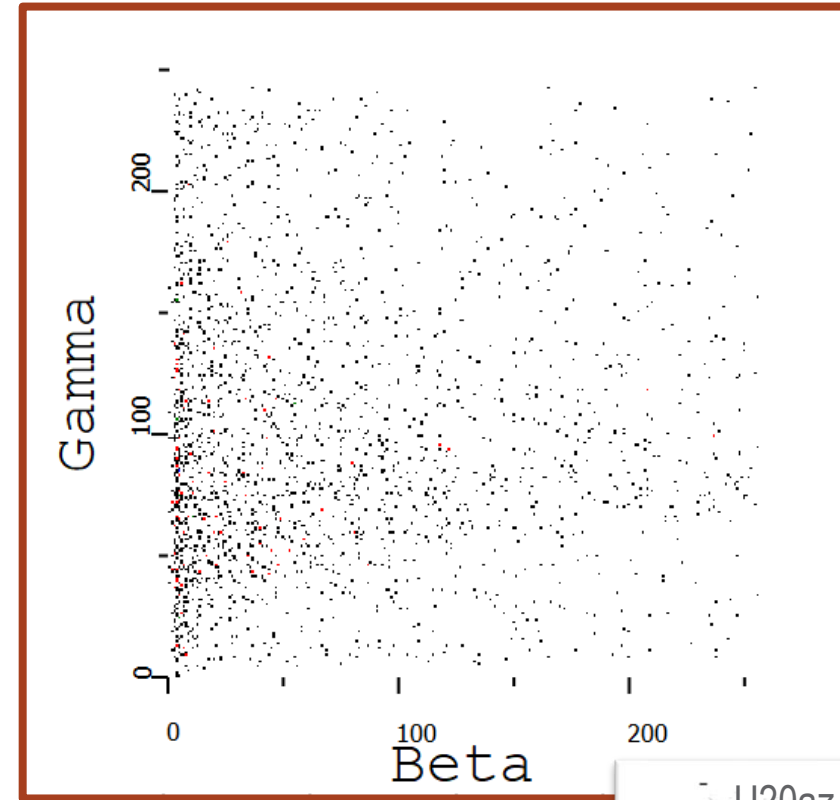

# Measurements on Aqueduct Mesa

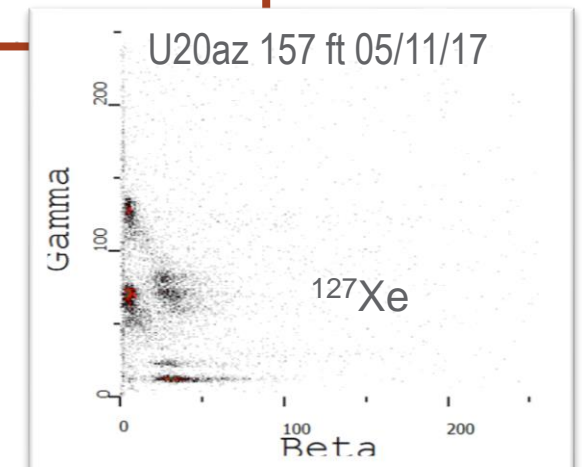

High levels of  $^{39}\text{Ar}$  impact  $^{37}\text{Ar}$  detection limits in the mesa borehole samples

Borehole Zone 1 10/15/18

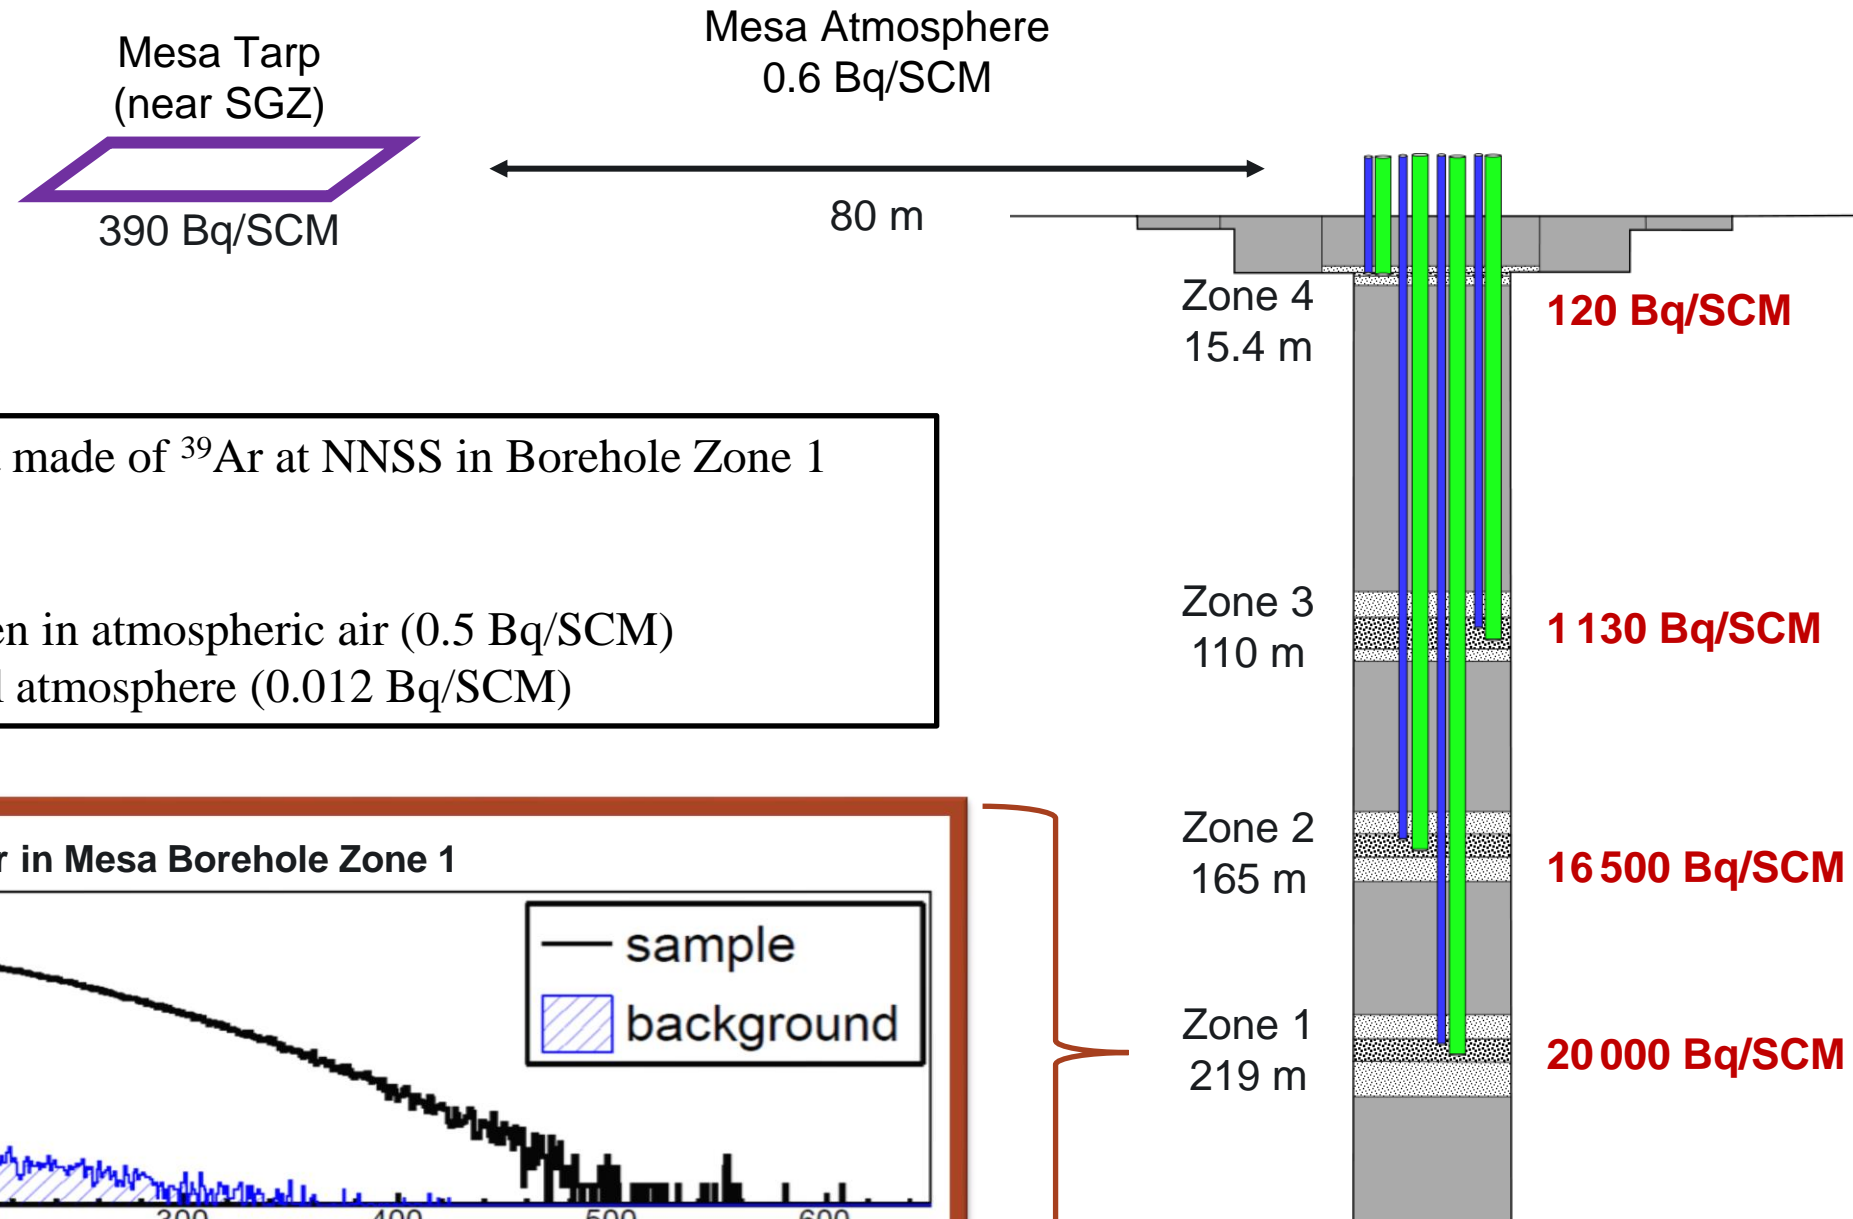

For comparison...

No detections of injected tracers in the deep borehole as of October 2018

# Measurements of $^{39}\text{Ar}$ on Aqueduct Mesa

- Highest measurements yet made of  $^{39}\text{Ar}$  at NNSS in Borehole Zone 1
  - **20 000 Bq/SCM!**
- Elevated levels of  $^{39}\text{Ar}$  seen in atmospheric air (0.5 Bq/SCM)
  - Over 30 times typical atmosphere (0.012 Bq/SCM)

# Summary

- **Key finding:** natural transport mechanisms not sufficient to force transport of injected tracers from injection point to deep borehole in a four month period
- Demonstrated ability to utilize small volume samples (1 L) for measurement of radioactive argon and stable gases
- **Key finding: the activation product  $^{39}\text{Ar}$  is present in significant quantities in the subsurface 30 years after a UNE.**
  - This impacts  $^{37}\text{Ar}$  detection limits –  $^{39}\text{Ar}$  acts as a background
  - Near surface  $^{39}\text{Ar}$  measurements of nearly  $400\text{ Bq/m}^3$  air
  - Above ground measurements of  $^{39}\text{Ar}$  on Aqueduct Mesa greater than 30 times average atmospheric levels
  - Highest  $^{39}\text{Ar}$  measurement yet at NNSS:  $20\,000\text{ Bq/m}^3$  air

## Ongoing Work

- Large volume samples are still being analyzed for  $^{127}\text{Xe}$  and radioargon
- Small volume samples are being sent out for higher fidelity (ppt) analysis of Freon and  $\text{SF}_6$
- Follow-on work: Enhanced Noble Gas Signatures Study
  - Developing model of  $^{39}\text{Ar}$  transport in a range of geologies
  - Improve analysis fidelity of  $^{127}\text{Xe}$  and  $^{39}\text{Ar}$
  - Developing model of P-tunnel which will be used to simulate both gas injections

*The Underground Nuclear Explosion Signatures Experiment (UNESE) was created to apply a broad range of research and development (R&D) techniques and technologies to nuclear explosion monitoring and nuclear nonproliferation. It is a multi-year research and development project sponsored by NNSA DNN R&D, and is collaboratively executed by Lawrence Livermore National Laboratory, Los Alamos National Laboratory, Mission Support and Test Services, Pacific Northwest National Laboratory, and Sandia National Laboratories.*
